# Total Variation and Image Processing

**Lab Objective:** Minimizing an energy functional is equivalent to solving the resulting Euler-Lagrange equations. We introduce the method of steepest descent to solve these equations, and apply this technique to a denoising problem in image processing.

## The Gradient Descent method

Consider an energy functional J[u], defined over a collection of admissible functions  $u:\Omega\subset\mathbb{R}^n\to\mathbb{R}$ , with the form

$$J[u] = \int_{\Omega} L(x, u, \nabla u) \, dx$$

where  $L = L(x, u, \nabla u)$  is a function  $\mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}$ . A standard result from the calculus of variations states that a minimizing function  $u^*$  satisfies the Euler-Lagrange equation

$$L_{u} - \sum_{i=1}^{n} \frac{\partial L_{u_{x_{i}}}}{\partial x_{i}} = L_{u} - \nabla \cdot L_{\nabla u} = L_{u} - \operatorname{div}(L_{\nabla u}) = 0.$$
(18.1)

where  $L_{\nabla u} = \nabla' L = [L_{x_1}, \dots, L_{x_n}]^{\mathsf{T}}$ .

This equation is typically an elliptic PDE, possessing boundary conditions associated with restrictions on the class of admissible functions u. To more easily compute (18.1), we consider a related parabolic PDE,

$$u_t = -(L_y - \operatorname{div} L_{\nabla u}), \quad t > 0,$$
  
 $u(x, 0) = u_0(x), \quad t = 0.$  (18.2)

A steady state solution of (18.2) does not depend on time, and thus solves the Euler-Lagrange equation. It is often easier to evolve an initial guess using (18.2), and stop whenever its steady state is well-approximated, than to solve (18.1) directly.

Consider the energy functional

$$J[u] = \int_{\Omega} \|\nabla u\|^2 \, dx.$$

The minimizing function  $u^*$  satisfies the Euler-Lagrange equation

$$-\operatorname{div} \nabla u = -\Delta u = 0.$$

The gradient descent flow is the well-known heat equation

$$u_t = \Delta u$$
.

The Euler-Lagrange equation could equivalently be described as  $\Delta u = 0$ , leading to the PDE  $u_t = -\Delta u$ . Since the backward heat equation is ill-posed, it would not be helpful in a search for the steady-state.

Let us take the time to make (18.2) more rigorous. We recall that

$$\delta J(u;h) = \frac{d}{dt} J(u + \varepsilon h) \bigg|_{\varepsilon=0},$$

$$= \int_{\Omega} (L_y(u) - \operatorname{div} L_{\nabla u}(u)) h \, dx,$$

$$= \langle L_y(u) - \operatorname{div} L_{\nabla u}(u), h \rangle_{L^2(\Omega)},$$

for each u and each admissible perturbation h. Then using the Cauchy-Schwarz inequality,

$$|\delta J(u;h)| \le ||L_y(u) - \operatorname{div} L_{\nabla u}(u)|| \cdot ||h||$$

with equality iff  $h = \alpha(L_y(u) - \operatorname{div} L_{\nabla u}(u))$  for some  $\alpha \in \mathbb{R}$ . This implies that the "direction"  $h = L_y(u) - \operatorname{div} L_{\nabla u}(u)$  is the direction of steepest ascent and maximizes  $\delta J(u; h)$ . Similarly,

$$h = -(L_u(u) - \operatorname{div} L_{\nabla u}(u))$$

points in the direction of steepest descent, and the flow described by (18.2) tends to move toward a state of lesser energy.

### Minimizing the area of a surface of revolution

The area of the surface obtained by revolving a curve y(x) about the x-axis is

$$A[y] = \int_{a}^{b} 2\pi y \sqrt{1 + (y')^{2}} \, dx.$$

To minimize the functional A over the collection of smooth curves with fixed end points  $y(a) = y_a$ ,  $y(b) = y_b$ , we use the Euler-Lagrange equation

$$0 = 1 - y \frac{y''}{1 + (y')^2},$$
  
= 1 + (y')^2 - yy'', (18.3)

with the gradient descent flow given by

$$u_{t} = -1 - (y')^{2} + yy'', \quad t > 0, \ x \in (a, b),$$

$$u(x, 0) = g(x), \quad t = 0,$$

$$u(a, t) = y_{a}, \quad u(b, t) = y_{b}.$$
(18.4)

### Numerical Implementation

We will construct a numerical solution of (18.4) using the conditions y(-1) = 1, y(1) = 7. A simple solution can be found by using a second-order order discretization in space with a simple forward Euler step in time. We create the grid and set our end states below.

```
import numpy as np
a, b = -1, 1.
alpha, beta = 1., 7.
#### Define variables x_steps, final_T, time_steps ####
delta_t, delta_x = final_T/time_steps, (b-a)/x_steps
x0 = np.linspace(a,b,x_steps+1)
```

Most numerical schemes have a stability condition that must be satisfied. Our discretization requires that  $\frac{\Delta t}{(\Delta x)^2} \leq \frac{1}{2}$ . We continue by checking that this condition is satisfied, and use the straight line connecting the end points as initial data.

```
# Check a stability condition for this numerical method
if delta_t/delta_x**2. > .5:
    print("stability condition fails")

u = np.empty((2,x_steps+1))
u[0] = (beta - alpha)/(b-a)*(x0-a) + alpha
u[1] = (beta - alpha)/(b-a)*(x0-a) + alpha
```

Finally, we define the right hand side of our difference scheme, and time step until the scheme converges.

```
def rhs(y):
    # Approximate first and second derivatives to second order accuracy.
    yp = (np.roll(y,-1) - np.roll(y,1))/(2.*delta_x)
    ypp = (np.roll(y,-1) - 2.*y + np.roll(y,1))/delta_x**2.
    # Find approximation for the next time step, using a first order Euler step
    y[1:-1] -= delta_t*(1. + yp[1:-1]**2. - 1.*y[1:-1]*ypp[1:-1])

# Time step until successive iterations are close
iteration = 0
while iteration < time_steps:
    rhs(u[1])
    if norm(np.abs((u[0] - u[1]))) < 1e-5: break
    u[0] = u[1]
    iteration+=1

print("Difference in iterations is ", norm(np.abs((u[0] - u[1]))))
print("Final time = ", iteration*delta_t)</pre>
```

**Problem 1.** Using 20 x steps, 250 time steps, a = -1, b = 1,  $\alpha = 1$ ,  $\beta = 7$ , and a final time of 0.2, plot the solution that minimizes (18.4). It should match figure 18.1.

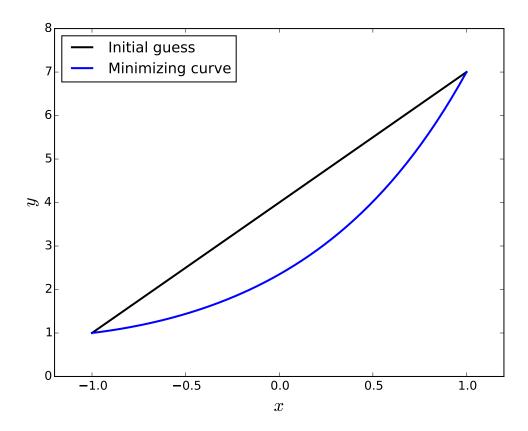

Figure 18.1: The solution of (18.3), found using the gradient descent flow (18.4).

# Image Processing: Denoising

A greyscale image can be represented by a scalar-valued function  $u: \Omega \to \mathbb{R}$ ,  $\Omega \subset \mathbb{R}^2$ . The following code reads an image into an array of floating point numbers, adds some noise, and saves the noisy image.

```
from numpy.random import randint, uniform, randn
import matplotlib.pyplot as plt
from matplotlib import cm
from imageio import imread, imwrite

imagename = 'baloons_resized_bw.jpg'
changed_pixels=40000
# Read the image file imagename into an array of numbers, IM
# Multiply by 1. / 255 to change the values so that they are floating point
# numbers ranging from 0 to 1.
IM = imread(imagename, as_gray=True) * (1. / 255)
IM_x, IM_y = IM.shape

for lost in range(changed_pixels):
```

```
x_,y_ = randint(1,IM_x-2), randint(1,IM_y-2)
val = .1*randn() + .5
IM[x_,y_] = max( min(val,1.), 0.)
imwrite("noised_"+imagename, IM)
```

A color image can be represented by three functions  $u_1, u_2$ , and  $u_3$ . In this lab we will work with black and white images, but total variation techniques can easily be used on more general images.

### A simple approach to image processing

Here is a first attempt at denoising: given a noisy image f, we look for a denoised image u minimizing the energy functional

$$J[u] = \int_{\Omega} L(x, u, \nabla u) dx, \qquad (18.5)$$

where

$$L(x, u, \nabla u) = \frac{1}{2}(u - f)^2 + \frac{\lambda}{2}|\nabla u|^2,$$
  
=  $\frac{1}{2}(u - f)^2 + \frac{\lambda}{2}(u_x^2 + u_y^2)^2.$ 

This energy functional penalizes 1) images that are too different from the original noisy image, and 2) images that have large derivatives. The minimizing denoised image u will balance these two different costs.

Solving for the original denoised image u is a difficult inverse problem-some information is irretrievably lost when noise is introduced. However, a priori information can be used to guess at the structure of the original image. For example, here  $\lambda$  represents our best guess on how much noise was added to the image, and is known as a regularization parameter in inverse problem theory.

The Euler-Lagrange equation corresponding to (18.5) is

$$L_u - \operatorname{div} L_{\nabla u} = (u - f) - \lambda \Delta u,$$
  
= 0.

and the gradient descent flow is

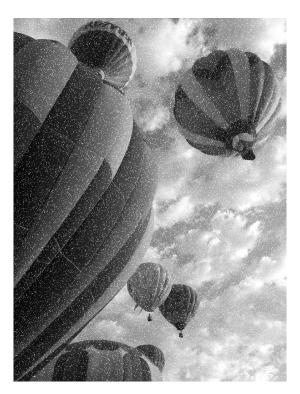

$$u_t = -(u - f - \lambda \Delta u),$$
  

$$u(x, 0) = f(x).$$
(18.6)

Let  $u_{ij}^n$  represent our approximation to  $u(x_i, y_j)$  at time  $t_n$ . We will approximate  $u_t$  with a forward Euler difference, and  $\Delta u$  with centered differences:

$$\begin{split} u_t &\approx \frac{u_{ij}^{n+1} - u_{ij}^n}{\Delta t}, \\ u_{xx} &\approx \frac{u_{i+1,j}^n - 2u_{ij}^n + u_{i-1,j}^n}{\Delta x^2}, \\ u_{yy} &\approx \frac{u_{i,j+1}^n - 2u_{ij}^n + u_{i,j-1}^n}{\Delta y^2}. \end{split}$$

Original image

Image with white noise

Figure 18.2: Noise.

**Problem 2.** Using  $\Delta t = 1e-3$ ,  $\lambda = 40$ ,  $\Delta x = 1$ , and  $\Delta y = 1$ , implement the numerical scheme mentioned above to obtain a solution u. (So  $\Omega = [0, n_x] \times [0, n_y]$ , where  $n_x$  and  $n_y$  represent the number of pixels in the x and y dimensions, respectively.) Take 250 steps in time. Plot the original image as well as the image with noise. Compare your results with Figure 18.3.

Hint: Use the function np.roll to compute the spatial derivatives. For example, the second derivative can be approximated at interior grid points using

```
u_xx = np.roll(u,-1,axis=1) - 2*u + np.roll(u,1,axis=1)
```

# Image Processing: Total Variation Method

We represent an image by a function  $u:[0,1]\times[0,1]\to\mathbb{R}$ . A  $C^1$  function  $u:\Omega\to\mathbb{R}$  has bounded total variation on  $\Omega$   $(BV(\Omega))$  if  $\int_{\Omega}|\nabla u|<\infty$ ; u is said to have total variation  $\int_{\Omega}|\nabla u|$ . Intuitively, the total variation of an image u increases when noise is added.

Initial diffusion-based approach

Total variation based approach

Figure 18.3: The solutions of (18.6) and (18.11), found using a first order Euler step in time and centered differences in space.

The total variation approach was originally introduced by Ruding, Osher, and Fatemi<sup>1</sup>. It was formulated as follows: given a noisy image f, we look to find a denoised image u minimizing

$$\int_{\Omega} |\nabla u(x)| \, dx \tag{18.7}$$

subject to the constraints

$$\int_{\Omega} u(x) dx = \int_{\Omega} f(x) dx,$$
(18.8)

$$\int_{\Omega} |u(x) - f(x)|^2 dx = \sigma |\Omega|. \tag{18.9}$$

Intuitively, (18.7) penalizes fast variations in f - this functional together with the constraint (18.8) has a constant minimum of  $u = \frac{1}{|\Omega|} \int_{\Omega} u(x) dx$ . This is obviously not what we want, so we add a constraint (18.9) specifying how far u(x) is required to differ from the noisy image f. More precisely, (18.8) specifies that the noise in the image has zero mean, and (18.9) requires that a variable  $\sigma$  be chosen a priori to represent the standard deviation of the noise.

Chambolle and Lions proved that the model introduced by Rudin, Osher, and Fatemi can be formulated equivalently as

$$F[u] = \min_{u \in BV(\Omega)} \int_{\Omega} |\nabla u| + \frac{\lambda}{2} (u - f)^2 dx, \qquad (18.10)$$

<sup>&</sup>lt;sup>1</sup>L. Rudin, S. Osher, and E. Fatemi, "Nonlinear total variation based noise removal algorithms", *Physica D.*, 1992.

where  $\lambda > 0$  is a fixed regularization parameter<sup>2</sup>. Notice how this functional differs from (18.5):  $\int_{\Omega} |\nabla u|$  instead of  $\int_{\Omega} |\nabla u|^2$ . This turns out to cause a huge difference in the result. Mathematically, there is a nice way to extend F and the class of functions with bounded total variation to functions that are discontinuous across hyperplanes. The term  $\int |\nabla|$  tends to preserve edges/boundaries of objects in an image.

The gradient descent flow is given by

$$u_{t} = -\lambda(u - f) + \frac{u_{xx}u_{y}^{2} + u_{yy}u_{x}^{2} - 2u_{x}u_{y}u_{xy}}{(u_{x}^{2} + u_{y}^{2})^{3/2}},$$

$$u(x, 0) = f(x).$$
(18.11)

Notice the singularity that occurs in the flow when  $|\nabla u| = 0$ . Numerically we will replace  $|\nabla u|^3$  in the denominator with  $(\varepsilon + |\nabla u|^2)^{3/2}$ , to remove the singularity.

**Problem 3.** Using  $\Delta t = 1e - 3$ ,  $\lambda = 1$ ,  $\Delta x = 1$ , and  $\Delta y = 1$ , implement the numerical scheme mentioned above to obtain a solution u. Take 200 steps in time. Display both the diffusion-based and total variaton images of the balloon. Compare your results with Figure 18.3. How small should  $\varepsilon$  be?

Hint: To compute the spatial derivatives, consider the following:

```
u_x = (np.roll(u,-1,axis=1) - np.roll(u,1,axis=1))/2
u_xx = np.roll(u,-1,axis=1) - 2*u + np.roll(u,1,axis=1)
u_xy = (np.roll(u_x,-1,axis=0) - np.roll(u_x,1,axis=0))/2.
```
